

Security risk assessment report

Part 1: Select up to three hardening tools and methods to implement

1.Firewall Maintenance: This is making sure the rules configured in the firewall are up to date and stay ahead of potential threats.

2.Password Policies: the password policy should be updated to make the passwords stronger and not easiest to guess by threat actors. It should have some length, special required characters included. And also they should be a disclaimer warning users not to share their password.

3.Implementing MFA: here is where users will be required to pass through at least two authentication processes before having access to an application.

Part 2: Explain your recommendations

Maintaining Firewalls regularly will keep the organisation's network protected from possible latest network threats. So network administrators should check and update firewalls regularly to know the type of the traffic it denies and the one it allows.

Password Policies is one of the most important tools that prevents attackers from hacking our system. If an organisation has strong password policies it makes threat actors find it difficult to guess or trial the user's password using brute force. It also helps attackers from trying too many attempts after some number of trials.

Multifactor Authentication is a vital tool which the organisation should consider because it prevents any unauthorized access since the user needs to go through at least two phases of identification like pins, face id's, otp codes, fingerprint etc. This prevents attacks like brute force attack because the hacker needs to go through more than one identification method which wouldn't be easy for them.
